

vynat property does a network need to have in order for closeness centrality to be well-defined?

The network must be connected for closeness centrality to be properly defined.

This indicates that there must exist a route for every two nodes in the network. If certain nodes cannot reach others, then the distances between those nodes become infinite, and the closeness centrality cannot be accurately determined.

▶ Solution

✓ Q3: Closeness and Betweeness (5 points)

Status Answered

Your score 0 / 5 0%

Response

Provide examples of networks such that;

- 1. The node with the highest degree is not the one with the largest closeness
- 2. The node with the highest betweenness is not the one with the largest closeness

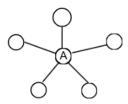

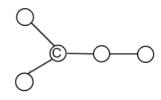

Diagram 2

Solution

■ Q4: Avg Neigbors and Avg Degree (5 points)

Status	Answered	
Your score	0/5	0%

Response

Are there networks such that the average number of neighbors of a node's neighbors matches the average degree? If there are, what property must they have?

Yes, there are networks where the average number of connections the neighbors of a given node have is equal to the average degree of the network. In these cases, the network must be regular.

Such a network is also termed as a regular network - a network in which every node has the same number of neighbors, that is, all the nodes have uniform degree. In such networks, because all nodes have the same degree with their neighbors, the average degree of neighbors equals the average degree of the network.

On the contrary, in most real-life networks, high-degree nodes tend to have more neighbors. This means that the average degree of neighbors is almost always greater than the average degree of the network. This phenomenon is known as the friendship paradox.

■ Q5: Vulnerability to Attacks (5 points)

Status	Answered	
Your score	0/5	0%

Response

Are networks with heavy tailed degree distributions more vulnerable to random or targeted attacks? And what about grid-like networks of similar size?

In networks exhibiting degree distributions with heavy tails, such as social networks or the internet, a few nodes (hubs) have an especially high number of connections, while the majority of other nodes possess very few connections. These networks possess a greater degree of structural integrity when randomly decimating nodes. Because random attacks are unlikely to remove any of the hubs, the structure remains intact and connected. Strongly directed attacks, however, will

erode the network's structure as deliberately removing the hubs causes the network disconnection to happen almost instantaneously.

Grid-like networks, where each node connects to a roughly equal number of nodes—like a lattice or road map—do not have hubs at all. As such, random and targeted attacks on these networks will have an equal effect. Each node holds the same value, meaning removing any node will cause localized structure damage, but overall, damage occurs more gradually.

In short:

Heavy-tailed networks are resistant to random failure, but are fragile under targeted attacks.

Grid-like networks possess uniform vulnerability, with no particular weaknesses to either type of attack.

◆ Solution

••• Q7: Mode, Clique, Hubs (20 points)

Status Answered

Your score 20 / 20 100%

Response

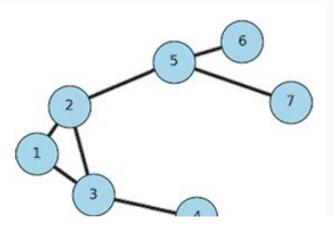

Consider a network formed by 250 students in a dormitory. The links in this network represent room-mate relationships: two nodes are connected if they are currently room-mates. In this dorm, the rooms are mostly double occupancy with a few triples and quads.

- Is this graph connected? (yes or no) no
- 2. What is the mode (most frequent value) of the node degree distribution? (numeric answer, e.g. 1, 2, 3,etc) 1.0
- 3. How many nodes are in the largest clique? (numeric answer) $\boxed{4.0}$
- 4. Would you expect this graph to have any hubs? (yes or no) no
- ▶ Solution

••• Q8: Degree, Closeness, Betweeness (15 points) Status Answered Your score 10 / 15 67%

Response

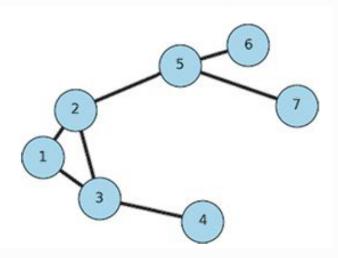

Consider the network of following figure in order to answer the next few questions. For each question, in case of a tie, answer with all the tied top nodes.

- 1. Which node(s) have the highest degree centrality? (If more than one node, use commas to list the node in numerical order) 2, 5
- 2. Which node(s) have the highest betweenness centrality? (If more than one node, use commas to list the node in numerical order)
- 3. Which node has the highest closeness centrality? 2

▼ Solution

Consider the network of following figure in order to answer the next few questions. For each question, in case of a tie, answer with all the tied top nodes.

- 1. Which node(s) have the highest degree centrality? (If more than one node, use commas to list the node in numerical order) 2,3,5
- 2. Which node(s) have the highest betweenness centrality? (If more than one node, use commas to list the node in numerical order) 2,5 2,5
- 3. Which node has the highest closeness centrality? 2

■ Q9: Centrality (5 points) Status Answered Your score 0 / 5 0%

Response

In NetworkX, how can you find a node with the largest degree of centrality in a network? And how would you also get the degree of that node?

To find the node with the largest degree centrality in a NetworkX graph, we can use the degree_centrality() function, which returns a dictionary mapping each node to its degree centrality value. To get the node with the highest value and its degree centrality, we can use the max() function with the dictionary's items() method. import networkx as nx

```
Python Programm :
G = nx.Graph()
G.add_edges_from([(1, 2), (1, 3), (2, 4), (3, 4), (4, 5)])

centrality = nx.degree_centrality(G)
max_node = max(centrality, key=centrality.get)
max_centrality = centrality[max_node]
node_degree = G.degree[max_node]

print(f"Node with highest degree centrality: {max_node}")
print(f"Degree centrality: {max_centrality}")
print(f"Degree: {node_degree}")
```
